Creating AWS account

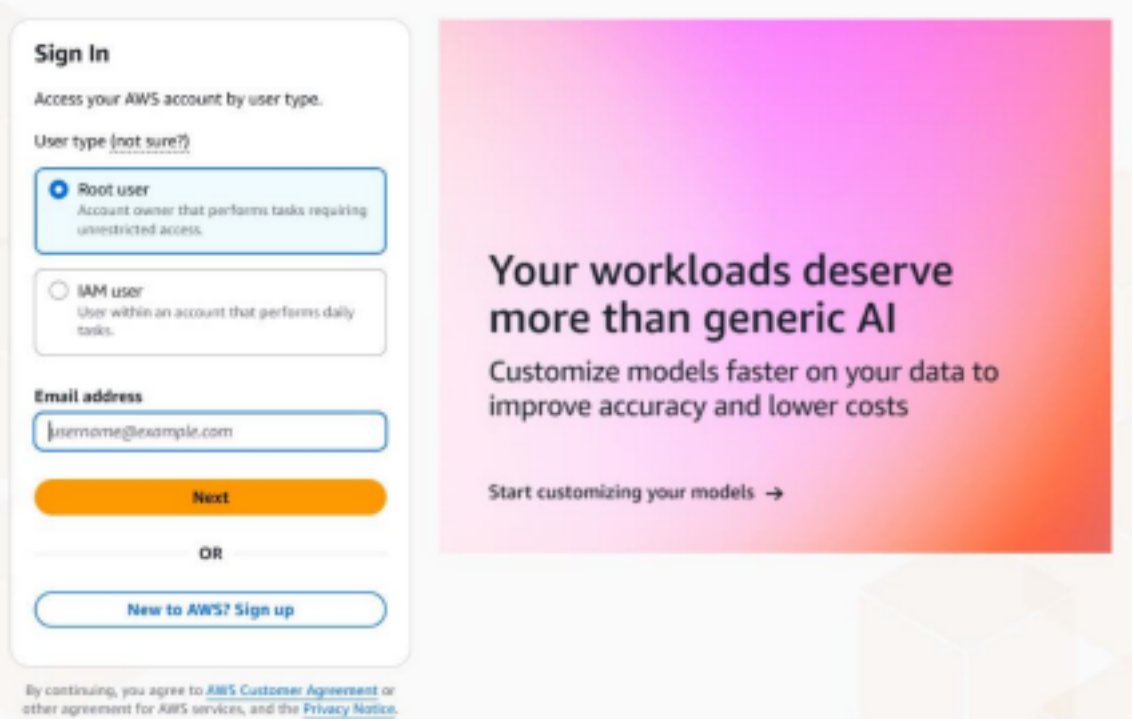

AWS Web Server

Creating an AWS account and accessing AWS services.
Create a free account to register, and **Start building in console** for existing users.

Clicking **Create a free account** moves the user to the sign-up flow.

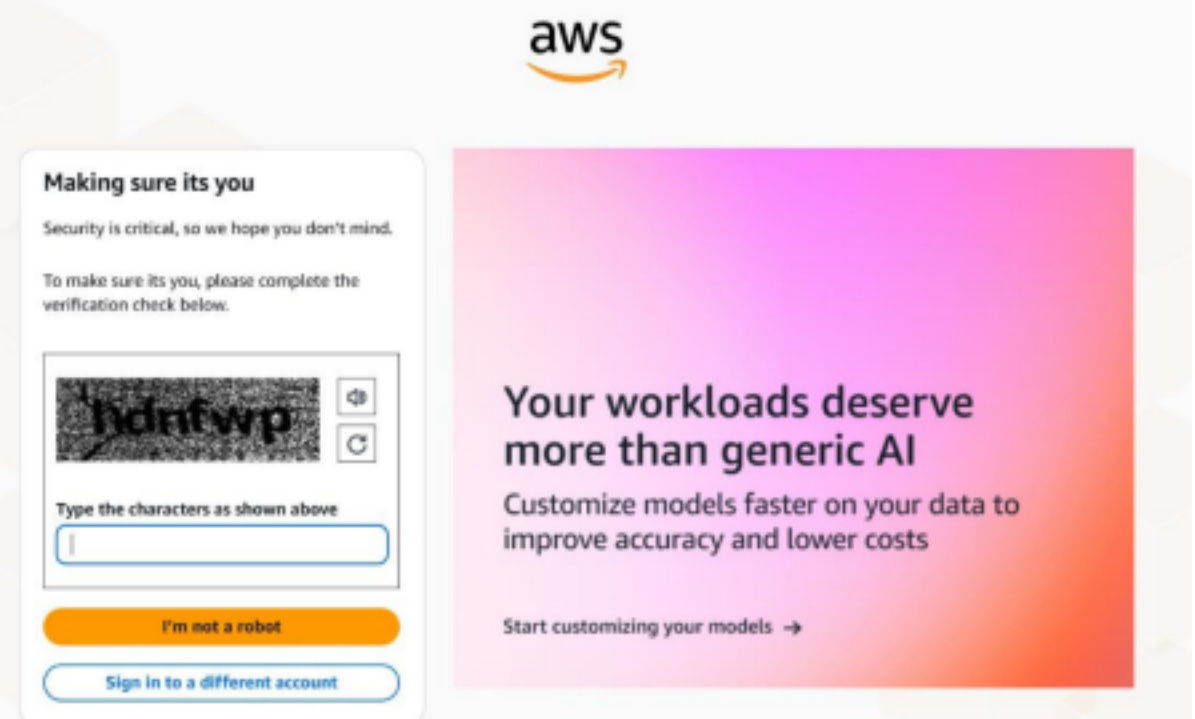

Sign Up

The AWS sign-in page is displayed, where the user enters an email address to begin the account registration process.

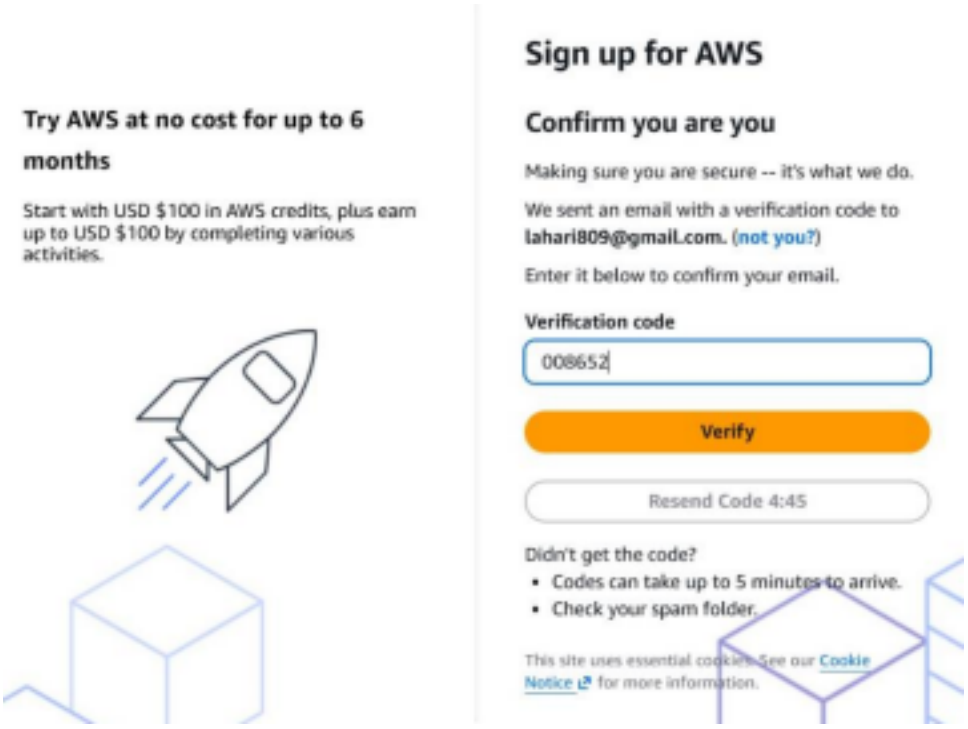

This page offers two user types. **Root user** is the account owner, who has unrestricted access to everything, while **IAM user** is a user created inside an account for day-to-day tasks. Since a brand-new account is being created, the user chooses **New to AWS? Sign up** at the bottom, and the email address entered here becomes the root user's identity for the account.

Email Check

AWS asks the user to verify that they are a real person before continuing.This is a CAPTCHA step, a security check meant to block automated bots from creating fake accounts. The user types the characters shown in the box and clicks **I'm not a robot**.

Verification

It confirms the email address by asking the user to enter the verification code received from AWS.
AWS emails a 6-digit verification code to the address given at sign-up. The user enters it in the **Verification code** field and clicks **Verify**, which proves they own that mailbox. The code stays valid for a short time, and a **Resend Code** button with a countdown timer is available. If the email does not arrive, the user should wait up to 5 minutes and check the spam folder. The side panel also mentions the free credits available to new accounts.

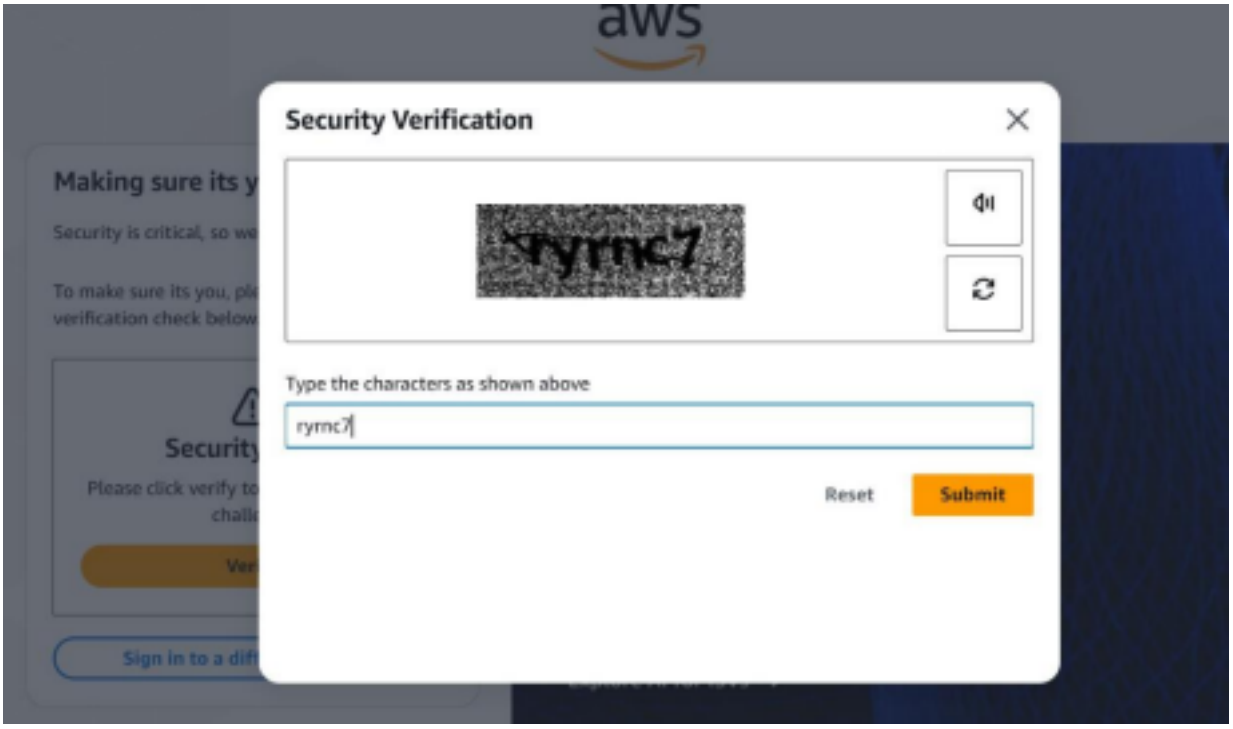

Sign Up for AWS: Contact Information

The AWS registration form, where the user provides the required account and contact details.

The user fills in the **Contact Information**. Clicking **Agree and Continue** saves these details and moves to the next stage.

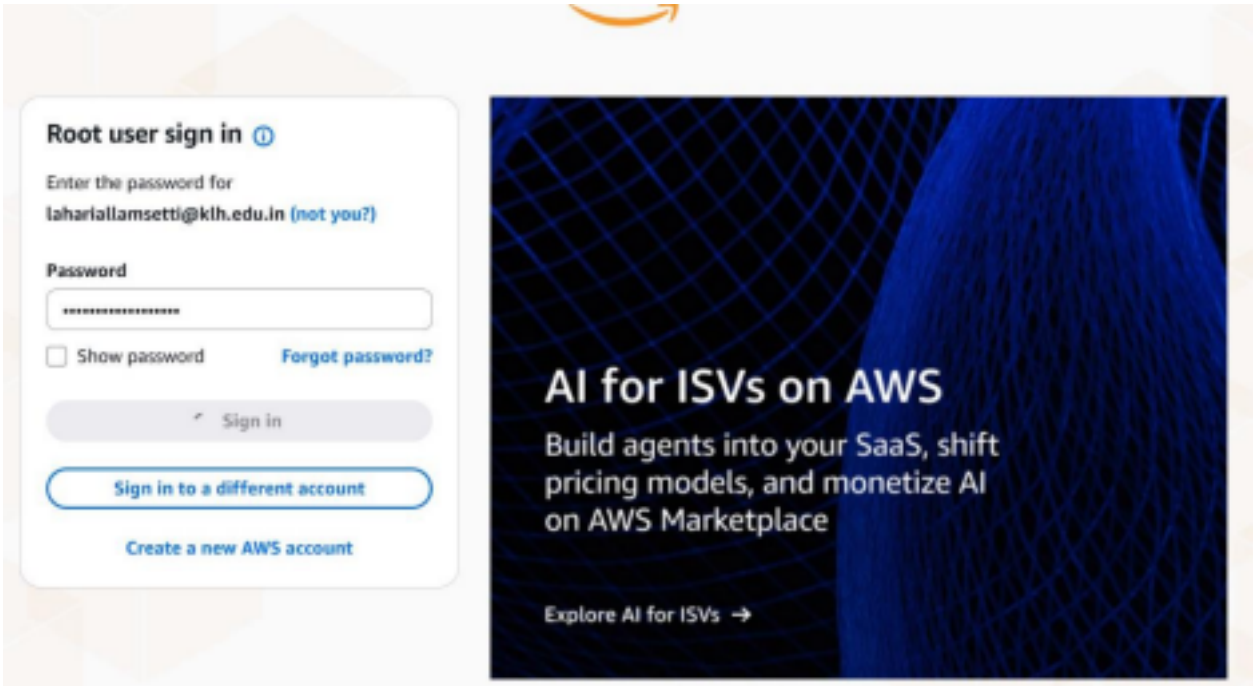

Security Verification

A security verification challenge is displayed. The user must enter the characters shown to continue creating the AWS account.

A second CAPTCHA pop-up appears as a final check before account creation continues. The user reads the distorted characters, types them into the text box and clicks **Submit**. **Reset** clears the field, and the audio and refresh buttons help if the image is unclear. Passing this check lets AWS proceed with setting up the account.

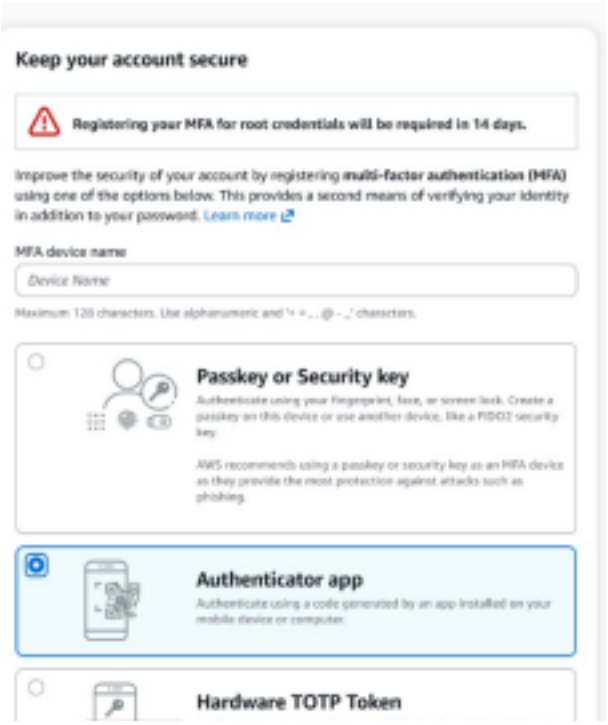

Root User Sign In

The AWS root user sign-in page is shown. It is used to access the account with the registered email address and password, before enabling multifactor authentication.

After the account has been created, the owner signs in as the **root user** by entering the registered email address and then the password. The root user has complete control over billing and every service, so this login must be well protected. The page also provides **Show password**, **Forgot password?** and **Sign in to a different account** options. Once signed in, AWS prompts the user to secure the account with multifactor authentication.

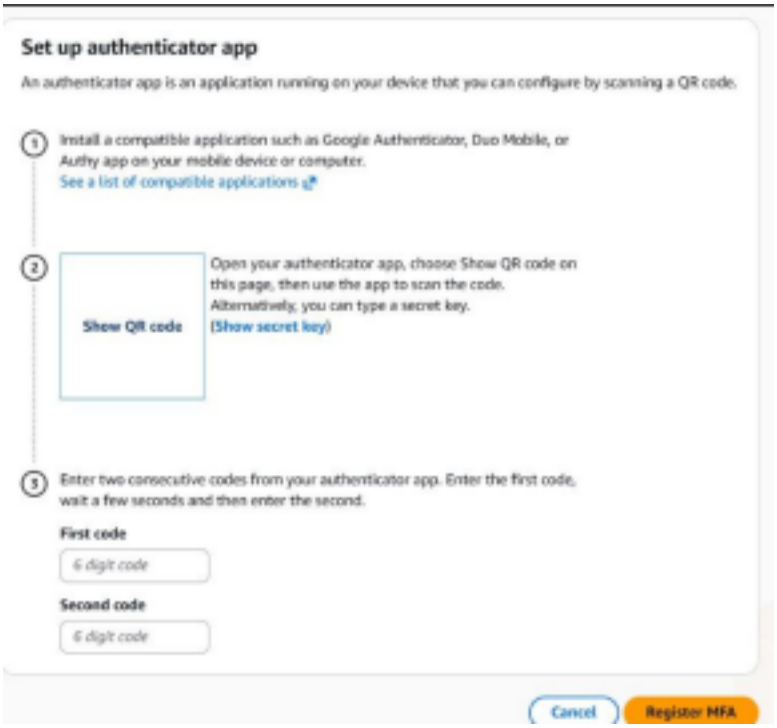

Applying Multifactor Authentication to AWS Account

The Authenticator app option is selected to add an extra layer of protection through multifactor authentication.

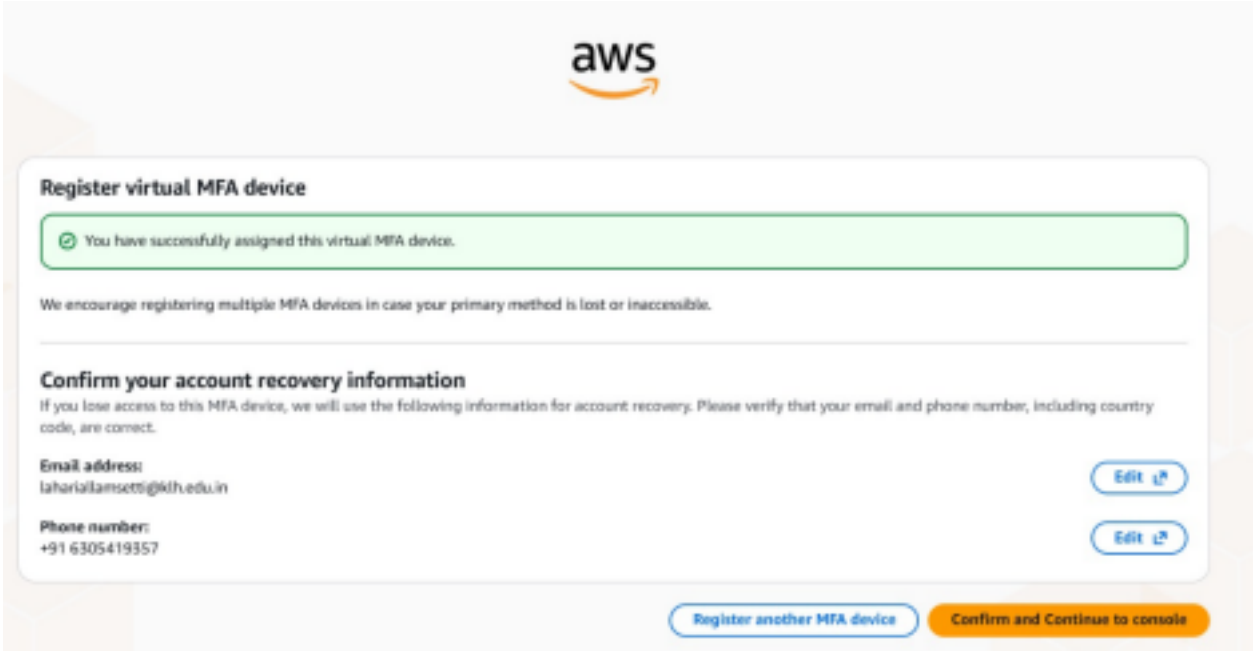

AWS shows a banner stating that registering MFA for root credentials will be required within 14 days. MFA adds a second proof of identity on top of the password, so a stolen password alone cannot open the account.

Set Up Authentication App

AWS displays instructions and a QR-code option for linking an authenticator app to the account. Linking the authenticator app takes three steps. First, install a compatible app such as Google Authenticator, Duo Mobile or Authy. Second, click **Show QR code** and scan it with the app; if scanning is not possible, **Show secret key** allows manual entry. Third, type two consecutive 6-digit codes from the app into the **First code** and **Second code** boxes and click **Register MFA**. Entering two codes in a row confirms that the app and AWS are properly synchronized.

Successfully Registered

The confirmation screen indicates that the virtual MFA device has been registered successfully and that the account security setup is complete.

The virtual MFA device was assigned to the account. From now on, signing in as the root user needs both the password and the current code from the authenticator app. AWS also asks the user to confirm the **account recovery information** (email address and phone number) that would be used if the MFA device were ever lost, and recommends registering more than one MFA device as a backup. Clicking **Confirm and Continue to console** completes the setup and opens the AWS Management Console.
